

CS 332 - Spring 2023  
A few Notes on Undecidability (so far)

1. A standard Turing Machine (TM) has an input alphabet  $\Sigma$  and has input strings  $x$  which are finite strings of symbols from  $\Sigma$ .

$M(x)$  = the result of TM  $M$  on input  $x$  = either "accept" or "reject" or "loop". (Here loop means "never halt" and the TM  $M$  may either actually loop on a finite part of its tape or run forever moving farther and farther along on its tape. )

2. The TM  $M$  recognizes a language  $L(M)$  defined by,  $L = \{x|x \text{ is an input string of } M \text{ and } M(x) \text{ accepts } \}$ .

Given a TM  $M$ , the language  $L(M)$  is a subset of  $\Sigma^*$  and is unique.

3. The language  $L$  is decidable if there is some TM  $M$  which recognizes  $L$  and which halts on every legal input string  $x$  for  $M$ .

In this case we say  $M$  accepts  $x$  if  $x \in L$  (i.e. "x is in L"), and otherwise it rejects  $x$ .

4. A language  $L$  is enumerable if there is a Turing machine with a printer which enumerates (lists) the elements of  $L$ .

$L$  is enumerable if and only if it is recognizable (Theorem 3.21).

5. A language is undecidable if there is no TM which decides it.

A language is unrecognizable if there is no TM which recognizes it.

6. Recall that a TM that decides a language  $L$  also recognizes  $L$ . It follows from this that if  $L$  is unrecognizable then  $L$  is undecidable.

7. The language  $A_{TM} = \{ \langle M, w \rangle \mid M \text{ is a TM that accepts the input string } w \}$ .

$A_{TM}$  is a language which is recognizable but  $A_{TM}$  is not decidable. In fact,  $A_{TM}$  is recognized by a UTM, a universal Turing Machine. UTM is not unique.

From this it follows that the complement of  $A_{TM} = \{ \langle M, w \rangle \mid M \text{ is a TM and } w \text{ is a legal input string for } M \text{ and } M \text{ does not accept the input string } w \}$  is not even recognizable.
